

REPLACEMENT ABSTRACT

Abstract

To simplify and speed up folding of plate-like elements (1) along a fold line (2), more particularly in a continuous operation, a method and a ~~device~~ an apparatus for folding plate-like elements (1) are proposed which ~~permit eliminating~~ eliminate the use of counter-impression elements in the region of the fold line (2). ~~In accordance with the invention~~ The apparatus includes a second impression device (6) that folds a second section (4) of the plate-like element (1) about the fold line (2) by a first force component oriented perpendicular to the plane of the second section (4). At the same time the second impression device (6) produces a second force component oriented in the plane of the second section (4) and acting in the direction of the fold line (2) ~~in urging~~ to urge a first section (3) of the plate-like element (1) against a first impression device (5).
